FIRE RESISTANCE OF CIRCULAR HOLLOW STEEL SECTIONS FILLED WITH BAR-REINFORCED CONCRETE

ABSTRACT

Experimental and theoretical studies have been carried out to predict the fire resistance of circular hollow steel columns filled with bar-reinforced concrete. A mathematical model to calculate the temperatures, deformations and the fire resistance of the columns is presented. Calculated results are compared with those measured. The results indicate that the model is capable of predicting the fire resistance of circular hollow steel columns, filled with bar-reinforced concrete, with an accuracy that is adequate for practical purposes.

FIRE RESISTANCE OF CIRCULAR HOLLOW STEEL SECTIONS FILLED WITH BAR-REINFORCED CONCRETE

1. INTRODUCTION

The use of hollow structural sections (HSS) has several benefits. Such sections are very efficient structurally in resisting compression loads. By filling these sections with concrete, a substantial increase in load-bearing capacity can be achieved and fire resistance can be obtained without the necessity of external fire protection for the steel. Eliminating steel surface protection also increases the usable space in a building.

For a number of years, the National Fire Laboratory of the Institute for Research in Construction, National Research Council of Canada, has also been engaged in studies to develop methods for predicting the fire resistance of these composite columns. These studies were supported by the Canadian Steel Construction Council and the American Iron and Steel Institute. A multi-phase program, which involves mathematical modelling and experiments, was established.

In the first phase, HSS filled only with plain concrete, were studied. These studies showed that substantial reductions in the loads on the columns have to be made to obtain reproducible and predictable fire resistances.

If the concrete is reinforced, however, the fire resistances remain predictable, even when very high loads are applied, as shown in studies on steel-bar reinforced concrete columns with or without steel encasing [1, 2].

In this report, a mathematical model for the prediction of the fire resistance of rectangular HSS columns, filled with bar-reinforced concrete, is presented and the results produced by this model and from those from tests are discussed.

2 CALCULATION PROCEDURE

The calculation of the fire resistance of the column is carried out in various steps. It involves the calculation of the temperatures of the fire to which the column is exposed, the temperatures in the column and its deformations and strength during the exposure to fire.

2.1 Temperatures of Column

The column temperatures are calculated by a finite difference method [3]. This method has been previously applied to the calculation of temperatures of various building components exposed to fire [4,5]. Because the method of deriving the heat transfer equations and of calculating the temperatures is described in detail in those studies, it will not be discussed here; only the equations for the calculation of the column temperatures will be given.

2.1.1 Division of Cross-Section into Layers

The cross-sectional area of the column is subdivided into a number of concentric layers. There are M_1 layers in the steel and $(M_2 - M_1 + 1)$ layers in the concrete. As illustrated in Figure 1, along any radius, a point P_m, representing the temperature of a

layer (m), is located at a distance of $(m-1)\Delta\xi_s$ from the fire-steel boundary when the point is in the steel, and at a distance of $(m-M_1)\Delta\xi_c$ from the concrete-steel boundary, when the point is in the concrete. The outer layer of the steel, which is exposed to fire, has a thickness of $1/2\Delta\xi_s$. The layer of steel at the boundary between steel and concrete is also $1/2\Delta\xi_s$ thick. The thickness of all other layers in the steel is $\Delta\xi_s$. The thickness of the layer of concrete at the boundary between steel and concrete, and that at the centre of the column is $1/2\Delta\xi_c$. The thickness of the other layers in the concrete is equal to $\Delta\xi_c$.

2.1.2 Equations for the Fire-Steel Boundary

It is assumed that the entire surface of the column is exposed to the heat of a fire whose temperature course follows that of the standard fire described in ASTM-E119 [6] or CAN4-S101 [7]. This temperature course can be approximately described by the following expression:

$$T_f^j = 20 + 750\left[1 - \exp\left(-3.79553\sqrt{\tau}\right)\right] + 170.41\sqrt{\tau} \tag{1}$$

where τ is the time in hours and T_f^j is the fire temperature in °C at time $\tau = j\Delta\tau$.

The temperature rise in the layer can be derived by creating a heat balance for each layer. In the following, all calculations will be carried out for a unit length of the column. For the layer at the exterior surface of the column, the temperature at time $t = (j+1)\Delta\tau$ is given by the expression:

$$T_1^{j+1} = T_1^j + \frac{2R_s\Delta\tau}{(\rho_s c_s)_1^j\left(R_s - \frac{\Delta\xi_s}{4}\right)\Delta\xi_s}\left\{\sigma\varepsilon_s\varepsilon_f\left[\left(T_f^j + 273\right)^4 - \left(T_1^j + 273\right)^4\right]\right\}$$

$$- \frac{\Delta\tau\left(R_s - \frac{\Delta\xi_s}{2}\right)}{(\rho_s c_s)_1^j\left(R_s - \frac{\Delta\xi_s}{4}\right)(\Delta\xi_s)^2}\left[(k_s)_1^j + (k_s)_2^j\right]\left(T_1^j - T_2^j\right) \tag{2}$$

2.1.3 Equations for Inside the Steel

For the layers in the steel, except for the surface layer and the layer at the boundary of the steel and concrete, the temperature at time $\tau = (j+1)\Delta\tau$ is given by:

$$T_m^{j+1} = T_m^j + \frac{\Delta\tau}{2\,(\rho_s c_s)_m^j\left[R_s - (m-1)\Delta\xi_s\right](\Delta\xi_s)^2}$$

$$\left\{\left[R_s - \left(m - \frac{3}{2}\right)\Delta\xi_s\right]\left[(k_s)_{m-1}^j + (k_s)_m^j\right]\left(T_{m-1}^j - T_m^j\right)\right.$$

$$\left. - \left[R_s - \left(m - \frac{1}{2}\right)\Delta\xi_s\right]\left[(k_s)_m^j + (k_s)_{m+1}^j\right]\left(T_m^j - T_{m+1}^j\right)\right\} \tag{3}$$

2.1.4 Equations for the Steel-Boundary

For the layer at the boundary of the steel and the concrete, the temperature at time $\tau = (j + 1)\Delta\tau$ is given by:

$$T_{M_1}^{j+1} = T_{M_1}^j + \cfrac{\Delta\tau}{(\rho_s c_s)_{M_1}^j \left[R_s - \left(M_1 - \frac{5}{4}\right)\Delta\xi_s\right]\Delta\xi_s + \left[(\rho_c c_c)_{M_1}^j + \rho_w c_w \phi_{M_1}^j\right]\left(R_c - \frac{\Delta\xi_c}{4}\right)\Delta\xi_c}$$

$$\left\{\left[\cfrac{R_s - \left(M_1 - \frac{3}{2}\right)\Delta\xi_s}{\Delta\xi_s}\right]\left[(k_s)_{M_1-1}^j + (k_s)_{M_1}^j\right]\left(T_{M_1-1}^j - T_{M_1}^j\right)\right.$$

$$\left. - \cfrac{R_c - \frac{\Delta\xi_c}{2}}{\Delta\xi_c}\left[(k_c)_{M_1}^j + (k_c)_{M_1+1}^j\right]\left(T_{M_1}^j - T_{M_1+1}^j\right)\right\}$$

(4)

2.1.5 Equations for Inside the Concrete

For the layers in the concrete, except for the layer at the centre of the column and the layer at the boundary of the concrete and steel, the temperature at time $\tau = (j + 1)\Delta\tau$ is given by:

$$T_m^{j+1} = T_m^j + \cfrac{\Delta\tau}{2\left[(\rho_c c_c)_m^j + \rho_w c_w \phi_m^j\right]\left[R_c - (m - M_1)\Delta\xi_c\right](\Delta\xi_c)^2}$$

$$\left\{\left[R_c - \left(m - M_1 - \frac{1}{2}\right)\Delta\xi_c\right]\left[(k_c)_{m-1}^j + (k_c)_m^j\right]\left(T_{m-1}^j - T_m^j\right)\right.$$

$$\left.\left[R_c - \left(m - M_1 + \frac{1}{2}\right)\Delta\xi_c\right]\left[(k_c)_m^j + (k_c)_{m+1}^j\right]\left(T_m^j - T_{m+1}^j\right)\right\}$$

(5)

2.1.6 Equations for the Centre of the Concrete

For the centre layer, the temperature at time $\tau = (j + 1)\Delta\tau$ is given by:

$$T_{M_2}^{j+1} = T_{M_2}^j + \cfrac{2\Delta\tau}{\left[(\rho_c c_c)_{M_2}^j + \rho_w c_w \phi_{M_2}^j\right](\Delta\xi_c)^2}$$

$$\left[(k_c)_{M_2-1}^j + (k_c)_{M_2}^j\right]\left[T_{M_2-1}^j - T_{M_2}^j\right]$$

(6)

2.1.7 Effect of Moisture

The effect of moisture in the concrete on the column temperatures is taken into account by assuming that, in each layer, the moisture starts to evaporate when the

temperature reaches 100°C. In the period of evaporation, all the heat supplied to a layer is used for evaporation until the layer is dry.

For the concrete layer at the boundary between steel and concrete, the initial volume of moisture is given by:

$$V_{M_1} = \pi \left(R_c - \frac{\Delta\xi_c}{4} \right) \Delta\xi_c \phi_{M_1} \tag{7}$$

From a heat balance equation, it can be derived that, per unit length of the column, the volume ΔV_{M_1} evaporated in the time $\Delta\tau$ from the concrete layer at the boundary steel-concrete, is:

$$\Delta V_{M_1}^j = \frac{\pi\Delta\tau}{\rho_w\lambda_w} \left\{ \frac{1}{\Delta\xi_s} \left[R_s - \left(M_1 - \frac{3}{2} \right)\Delta\xi_s \right] \left[(k_s)_{M_1-1}^j + (k_s)_{M_1}^j \right] \left[T_{M_1-1}^j - T_{M_1}^j \right] \right.$$

$$\left. - \frac{1}{\Delta\xi_c} \left(R_c - \frac{\Delta\xi_c}{2} \right) \left[(k_c)_{M_1}^j + (k_c)_{M_1+1}^j \right] \left(T_{M_1}^j - T_{M_1+1}^j \right) \right\} \tag{8}$$

For the concrete layers inside the column, except for the layer at the boundary between the steel and concrete and the centre layer, the initial volume of moisture is given by:

$$V_m = 2\pi \left[R_c - (m - M_1)\Delta\xi_c \right] \Delta\xi_c \phi_m \tag{9}$$

Similarly, as for the boundary concrete layer, it can be derived that, per unit length of the column, the volume ΔV_m^j, evaporated in time $\Delta\tau$ from these layers, is:

$$\Delta V_m^j = \frac{\pi\Delta\tau}{\rho_w\lambda_w\Delta\xi_c} \left\{ \left[R_c - \left(m - M_1 - \frac{1}{2} \right)\Delta\xi_c \right] \left[(k_c)_{m-1}^j + (k_c)_m^j \right] \left(T_{m-1}^j - T_m^j \right) \right.$$

$$\left. \left[R_c - \left(m - M_1 + \frac{1}{2} \right)\Delta\xi_c \right] \left[(k_c)_m^j + (k_c)_{m+1}^j \right] \left(T_m^j - T_{m+1}^j \right) \right\} \tag{10}$$

For the concrete centre layer, the initial volume of moisture is:

$$V_{M_2} = \pi \frac{(\Delta\xi_c)^2}{4} \phi_{M_2} \tag{11}$$

From a heat balance equation, it can be derived that, per unit length of the column, the volume ΔV_{M_2} evaporated in the time $\Delta\tau$ from the centre layer, is:

$$\Delta V_{M_2}^j = \frac{\pi\Delta\tau}{2\rho_w\lambda_w} \left[(k_c)_{M_2-1}^j + (k_c)_{M_2}^j \right] \left[T_{M_2-1}^j - T_{M_2}^j \right] \tag{12}$$

2.1.8 Stability Criteria

In order to ensure that any error existing in the solution at some time will not be amplified in subsequent calculations, a stability criterion has to be satisfied. For a selected value of $\Delta\xi$, this limits the maximum time step Δt. Following the method described in Reference [3], it can be derived that, for the fire-exposed columns, the criterion of stability is given by the smallest of the following three criteria of stability:

at boundary fire-steel:

$$\Delta\tau_1 = \frac{(\rho_s c_s)_{min} (\Delta\xi_s)^2}{2\left[h_{max}\Delta\xi_s + (k_s)_{max}\right]} \tag{13}$$

at boundary steel-concrete:

$$\Delta\tau_2 = \frac{\left\{(\rho_s c_s)_{min}\left[R_s - \left(M_1 - \frac{5}{4}\right)\Delta\xi_s\right]\Delta\xi_s + (\rho_c c_c)_{min}\left(R_c - \frac{\Delta\xi_c}{4}\right)\Delta\xi_c\right\}}{2\left\{\frac{\left[R_s - \left(M_1 - \frac{3}{2}\right)\Delta\xi_s\right]}{\Delta\xi_s}(k_s)_{max} + \frac{\left(R_c - \frac{\Delta\xi_c}{2}\right)}{\Delta\xi_c}(k_c)_{max}\right\}} \tag{14}$$

at the centre:

$$\Delta\tau_3 = \frac{(\rho_c c_c)_{min} (\Delta\xi_c)^2}{4 (k_c)_{max}} \tag{15}$$

In these equations, $(\rho_s c_s)_{min}$ and $(\rho_c c_c)_{min}$ are the minimum values of the heat capacity of the steel and concrete, $(k_s)_{max}$ and $(k_c)_{max}$ the maximum values of the thermal conductivity of steel and concrete and h_{max} the maximum value of the coefficient of heat transfer to be expected during the exposure to fire. For exposure to the standard fire, the maximum value of the coefficient of heat transfer h_{max} is approximately 675 W/m2°C.

2.1.9 Procedure for the Calculation of Column Temperatures

With the aid of Equations 1-15, and the relevant material properties given in the Appendix, the temperature distribution in the column and on its surface can be calculated for any time, $\tau = (j + 1)\Delta\tau$, if the temperature distribution at the time $j\Delta\tau$ is known. Starting from an initial temperature of 20°C, the temperature history of the column can be calculated by repeated application of Equations 1-15.

2.2 Strength of Column During Fire

2.2.1 Division of Cross-Section into Annular Elements

To calculate the deformations and stresses in the column and its strength, the cross-sectional area of the column is subdivided into a number of annular elements. In Figure 2,

the arrangement of the elements is shown in a quarter section of the column. The arrangement of the elements in the three other quarter sections is identical to this. In the radial direction, the sub-division is the same as that shown in Figure 1, where the cross-section is divided into concentric layers. In the tangential direction, each quarter section layer is divided into N elements. The temperature representative of that of an element is assumed to be equal to the temperature at its centre. It is obtained by taking the average of the temperatures at the tangential boundaries of each element, previously calculated with the aid of Equations 1-15.

Thus, for an element $P_{m,n}$, the representative temperature is:

$$\left(T^j_{m,n}\right)_{annular} = \left(\frac{T^j_m + T^j_{m+1}}{2}\right)_{layer}$$

(16)

where the subscripts, annular and layer, refer to the annular elements shown in Figure 2 and the element layers shown in Figure 1, respectively.

For the steel reinforcing bars, a representative bar temperature can be indicated also. Measurements at various locations in steel bar sections during fire tests showed that the differences in temperature in the bar sections are small [8]. A close approximation of the average bar temperature is obtained by considering the column as consisting entirely of concrete and selecting the temperature at the location of the centre of the bar section as the representative bar temperature. Thus, for a steel reinforcing bar, the centre of whose section is located in an element $P_{m,n}$, the representative temperature is equal to that of $P_{m,n}$, which is given by Eq. (10).

Similarly, it is assumed that the stresses and deformations at the centre of an element are representative of those of the whole element.

2.2.2 Assumptions in the Calculation of Strength During Fire

During exposure to fire, the strength of the column decreases with the duration of exposure. The strength of the column can be calculated by a method based on a load deflection or stability analysis [9].

In this method, the columns are idealized as pin-ended columns of effective length KL [Figure 3]. The load on the column is intended to be concentric. Due to imperfections of the columns and the loading device, some eccentricity exists. The loading system and the test columns were made with high precision, however. Therefore, in the calculations, a very small arbitrary load eccentricity of 0.2 mm, reflecting a nearly concentric load, has been selected for the initial eccentricity.

The curvature of the column is assumed to vary from pin-ends to midheight according to a straight line relation , as illustrated in Figure 3. For such a relation, the deflection at midheight Y, in terms of the curvature χ of the column at this height, can be given by:

$$Y = \chi \frac{(KL)^2}{12}$$

(17)

For any given curvature, and thus for any given deflection at midheight, the axial strain is varied until the internal moment at the mid-section is in equilibrium with the applied moment, i.e.,

$$\sum_{m,n} f_{m,n} A_{m,n} x_{m,n} = \sum_{m,n} f_{m,n} A_{m,n} (Y + e)$$

(18)

In this way, a load-deflection curve can be calculated for any specific time during the exposure to fire. From these curves, the strength of the column, i.e., the maximum load that the column can carry, can be determined for each time. In the calculation of column strength, the following assumptions were made:

1. The properties of the steel and concrete are those described in the Appendix.
2. Concrete has no tensile strength.
3. Plane sections remain plane.
4. There is no slip between steel and concrete.
5. There is no composite action between the steel and concrete.
6. The reduction in column length before exposure to fire (consisting of free shrinkage of the concrete, creep, and shortening of the column due to load) is negligible. This reduction can be eliminated by selecting the length of the shortened column as initial length from which the changes during exposure to fire are determined.

Based on these assumptions, the column strength during exposure to fire was calculated. In the calculations, the network of annular elements shown in Figure 2 was used. Because the strains and stresses of the elements are not symmetrical with respect to the y-axis, the calculations were performed for both the network shown and an identical network at the left of the y-axis. The load that the column can carry and the moments in the section were obtained by adding the loads carried by each element and the moments contributed by them.

2.2.3 Equations for the Concrete

The strain in the concrete for the elements to the right of the y-axis can be given by:

$$(\varepsilon_c)_R = -(\varepsilon_c)_T + \varepsilon + \frac{x_c}{\rho}$$

(19)

and for the elements to the left of the y-axis by:

$$(\varepsilon_c)_L = -(\varepsilon_c)_T + \varepsilon - \frac{x_c}{\rho}$$

(20)

where $(\varepsilon_T)_c$ = thermal expansion of concrete mm^{-1}

ε = axial strain of the column, mm^{-1}

x_c = horizontal distance from the centre of the element to a vertical plane through y-axis of the column section, m

ρ = radius of curvature, m

The stresses in the elements are calculated using the same stress-strain relations for concrete, given in Equations 25-30 in the Appendix.

2.2.4 Equations for the Steel

The strain in an element of the steel can be given as the sum of the thermal expansion of the steel $(\varepsilon_s)_T$, the axial strain of the column ε and the strain due to bending of the column x_s/ρ, where x_s is the horizontal distance of the steel element to the vertical plane through the y-axis of the column section and ρ is the radius of curvature. For the steel to the right of the y-axis (Figure 2), the strain $(\varepsilon_s)_R$ is given by:

$$(\varepsilon_s)_R = -(\varepsilon_s)_T + \varepsilon + \frac{x_s}{\rho} \tag{21}$$

For the steel elements to the left of the y-axis, the strain $(\varepsilon_s)_L$ is given by:

$$(\varepsilon_s)_L = -(\varepsilon_s)_T + \varepsilon - \frac{x_s}{\rho} \tag{22}$$

The stresses in the steel are calculated using the same stress-strain relations for steel, given by Equations 42-46 in the Appendix.

2.2.5 Equations for the Steel Reinforcement

The strain in the steel reinforcing bars can be given as the sum of the thermal expansion of the steel $(\varepsilon_T)_B$, the axial strain of the column x_B/ρ, where x_B is the horizontal distance of the centre of the section of steel bar to the vertical plane through the y-axis of the column section, and ρ is the radius of curvature. For the steel bars at the right of the y-axis, the strain $(\varepsilon_B)_R$, is given by:

$$(\varepsilon_B)_R = -(\varepsilon_T)_B + \varepsilon + \frac{x_B}{\rho} \tag{23}$$

For the steel bars at the left of the y-axis, the strain $(\varepsilon_B)_L$, is given by:

$$(\varepsilon_B)_L = -(\varepsilon_T)_B + \varepsilon - \frac{x_B}{\rho} \tag{24}$$

The stresses in the steel are calculated using the same stress-strain relations for steel, given by Equations 42-46 in the Appendix.

2.2.6 Procedure for the Calculation of Column Strength

With the aid of Equations 19-24, Equations 25-30 and Equations 42-46, the stresses at mid-section in the steel and concrete elements can be calculated for any value of the axial strain ε and curvature $1/\rho$. From these stresses, the load that each element carries and its contribution to the internal moment at mid-section can be derived. By adding the loads and moments, the load that the column carries and the total internal moment at mid-section can be calculated.

The fire resistance of the column is derived by calculating the strength of the column as a function of time of fire exposure. This strength reduces gradually with time.

At a certain point, the strength becomes so low that it is no longer sufficient to support the load. At this point, the column becomes unstable and is assumed to have failed. The time to reach this failure point is the fire resistance of the column.

3. TEST SPECIMENS

Two test specimens, consisting of circular hollow steel columns filled with reinforced carbonate aggregate concrete, were used to verify the model given in this report. The test specimens are described in detail in Reference 2 and are illustrated in Figure 4.

The two columns had the same dimensions. The columns were 3810 mm long from end plate to end plate. The outside diameter was 273.1 mm and the steel wall thickness was 6.35 mm. The steel end plates measured 508 mm wide by 610 mm long by 25 mm thick.

The steel columns were fabricated by cutting the steel to appropriate lengths. Steel and end plates were then welded at the column extremities. Accurate centering and perpendicularity of the end plates were given special attention. Before welding the end plates, a hole with a diameter 25.4 mm smaller than the inner diameter of the hollow steel section was cut in each plate. The smaller diameter of the holes created, after welding, a lip of 13 mm, as shown in Figure 5.

Four small holes were also drilled in the steel wall to provide vent holes for water vapour produced during the experiment. Two of the holes were located opposite one another at 1448 mm above midheight of the column. The other two were also located opposite to one another at 1448 mm below midheight of the column.

The steel of the columns was manufactured according to CSA Standard CAN3-G40.20-M81 [10], Class H and had a specified yield strength of 350 MPa.

Deformed bars, meeting the CSA Standard G30.12-M77 [11] with a minimum yield strength of 400 MPa, were used for the main reinforcing and tie bars. The diameter of the main reinforcing bars was 19.5 mm. The diameter of the ties was 6.4 mm.

The main reinforcing bars were tied together to complete the steel cage. The main bars were cut 10 mm shorter than the column length. The steel cage was then placed into the column with special care to ensure appropriate centering.

The concrete was poured in the column through the top opening. Its composition, per cubic metre of concrete mix, was as follows:

Cement	439 kg
Water	161 kg
Fine Aggregate	621 kg
Coarse Aggregate	1128 kg

The 28-day cylinder strength was approximately 42 MPa. The average cylinder strength at the time of testing was approximately 47 MPa.

Chromel-alumel thermocouples with a thickness of 0.91 mm were installed at midheight of the column for measuring the temperatures of the steel, reinforcement bars and concrete at different locations in the cross-section. The locations of the thermocouples are described in detail in Reference 2.

4. TEST APPARATUS

The tests were carried out by exposing the columns to heat in a column test furnace. The test furnace was designed to produce the conditions to which a member might be subjected during a fire. It consists of a steel framework supported by four steel columns, with the furnace chamber inside the framework. The characteristics and instrumentation of the furnace, which has a loading capacity of 1000 t, are described in detail in Reference 12.

5 TEST CONDITIONS AND PROCEDURES

5.1 End conditions

The tests were carried out with both ends of the columns fixed, i.e., restrained against rotation and horizontal translation. For this purpose, eight 19 mm bolts spaced regularly around the column were used at each end to bolt the end plates to the loading head at the top and the hydraulic jack at the bottom.

5.2 Loading

Both columns were tested under a concentric load. The applied loads were 37 and 67% of the factored compressive resistance of the columns (C_{rc}) or 95 and 171% of the factored compressive resistance of the concrete core (C'_r), determined according to CSA Standard CSA/CAN-S16.1-M89 [13]. The factored compressive resistances of each column, as well as the applied loads, are given in Table 1. The effective length factors, K, used in the calculation of the factored compressive resistances were those recommended in CSA/CAN-S16.1-M89 for the given end condition, i.e., 0.65. The effective length of the columns, KL, was thus assumed to be 2.48 m.

The load was applied for approximately 45 min before the start of the test, until a condition was reached at which no further increase of the axial deformation could be measured. This condition was selected as the initial condition for the column axial deformation. The load was maintained constant throughout the test.

5.3 Fire exposure

The ambient temperature at the start of each test was approximately 20°C. During the test, the column was exposed to heating controlled in such a way that the average temperature in the furnace followed as closely as possible the ASTM-E119 [6] or CAN/ULC-S101 [7] standard temperature-time curve.

5.4 Failure criterion

The columns were considered to have failed, and the tests terminated, when the hydraulic jack, which has a maximum speed of 76 mm/min, could no longer maintain the load.

5.5   Recording of results

The furnace, concrete and steel temperatures, as well as the axial deformations of the columns were recorded at 2-minute intervals.

6.   RESULTS AND DISCUSSION

Using the mathematical model described in this report, the temperatures, axial deformations and strengths of the columns were calculated. In the calculations, the thermal and mechanical properties of the concrete and steel, and the specifics of the column furnace given in the Appendix, were used.

In Figs. 6 and 7, calculated temperatures are compared with the temperatures measured at the steel surface of the steel section, and the temperatures at various depths in the concrete. It can be seen that, with the exception of the temperatures measured at an early stage, there is a good agreement between calculated and measured column temperatures. The temperatures measured deeper inside the column show initially a relatively rapid rise, followed by a period of relatively slow rate of temperature rise. This temperature behaviour may be the result of thermally induced migration of the moisture towards the centre of the column where, as shown in previous tests [2], the influence of migration is most pronounced. Although the model takes into account evaporation of moisture, it does not take into account the migration of the moisture towards the centre. That migration appears to account for the deviation between calculated and measured temperatures at the earlier stages of fire exposure. At a later stage, however, which is the important stage from the point of view of predicting the fire resistance of the columns, there is a good agreement between calculated and measured temperatures.

In Figs. 8 and 9, the calculated and measured axial deformations of the columns during exposure to fire are shown. It can be seen that there is reasonably good agreement in the trend of deformations between calculated and measured results. There are some differences, however, between the actual values of the calculated and measured deformations.

It must be noted that the column deforms axially as a result of several factors, namely, load, thermal expansion, bending and creep, which cannot be completely taken into account in the calculations. Since the axial deformations, which are on the order of 20 mm, are for columns with a length of about 3800 mm, small inaccuracies in these factors may cause noticeable differences between calculated and measured axial deformations. A difference of 10% between the theoretical and actual coefficients of thermal expansion of steel, for example, will cause a difference of approximately 5 mm in the axial deformations. The effect of creep, which is more pronounced at a later stage of the fire exposure, may be even greater. Whereas the model defines the failure point as the point at which the column can no longer support the applied load and assumes that failure at this point is instantaneous, during the tests, the columns contracted considerably, apparently as a result of continued loss of strength and creep, before they were crushed.

In Fig. 10, calculated column strengths as a function of the fire exposure time are shown, together with the calculated and measured fire resistances for the test loads given in Table 1. The strength decreases with time until it becomes so low that the column can no longer support the load. The time to reach this point is the fire resistance of the column. The calculated fire resistances of the columns are also given in Table 1 together with the measured fire resistances. The results show that the calculated fire resistance of Column No. 1 is about 20 percent and that of Column 2 about 10 percent lower than the measured fire resistances. The differences are probably caused mainly by the considerable

contraction of the columns, which the model can only partly take into account. For practical purposes, however, the calculated fire resistances are reasonably accurate.

7. CONCLUSIONS

Based on the results of this study, the following conclusions can be drawn:

1. The mathematical model employed in this study is capable of predicting the fire resistance of circular columns, made of HSS filled with bar-reinforced concrete, with an accuracy that is adequate for practical purposes. The results indicate that the model is conservative in its predictions.

2. The model will enable the expansion of data on the fire resistance of circular concrete filled steel columns, which at present consists predominantly of data for columns filled with plain concrete, with that for columns filled with bar reinforced concrete.

3. Using the model, the fire resistance of circular concrete filled steel columns can be evaluated for any value of the significant parameters, such as load, column section dimensions, column length and percentage of reinforcing steel, without the necessity of testing.

4. The model can also be used for the calculation of the fire resistance of columns made with concretes other than those investigated in this study, for example lightweight or siliceous aggregate concretes, if the relevant material properties are known.

NOMENCLATURE

A	area of element (m^2)
c	specific heat (J/kg°C)
e	eccentricity (m)
f	stress (MPa)
f'	cylinder strength of concrete at temperature T (MPa)
f'_{c0}	cylinder strength of concrete at room temperature (MPa)
f_y	strength of steel at temperature T (MPa)
h	coefficient of heat transfer at fire exposed surface (W/m^2°C)
k	thermal conductivity (W/m°C)
K	effective length factor
l	length of column that contributes to axial deformation (m)
L	unsupported length of the column (m)
M_1	number of points P in the steel section in radial direction
M_2	total number of points P in the column section in radial direction
N_1	number of elements in tangential direction
P	point
R_c	radius of concrete core (m)
R_s	radius of steel column (m)
T	temperature (°C)
V	volume of moisture in an element (m^3)
x	coordinate (m)
y	coordinate (m)
Y	lateral deflection of column at mid-height (m)

Greek Letters

α	coefficient of thermal expansion (1/°C)
Δ	increment or difference
$\Delta\xi$	mesh width in radial direction (m)
ε	emissivity, strain (m/m)
λ	heat of vaporization (J/kg)
ρ	density (kg/m^3), radius of curvature (m)
σ	Stefan-Boltzmann constant (W/m^{2}K^4)
τ	time (h)
ϕ	concentration of moisture
χ	curvature of column at mid-height (1/m)

Subscripts

0	at room temperature
B	of steel reinforcement
c	of concrete
f	of fire
L	left of the x-axis
m, M_1, M_2	at the points m, M_1, M_2 in radial direction
max	maximum
min	minimum
n, N_1	at the points n, N_1 in tangential direction
p	pertaining to proportional stress-strain relation
R	right of the x-axis
s	of steel
T	pertaining to temperature
w	of water

Superscripts

j	at $\tau = j\Delta\tau$

TABLE 1. SUMMARY OF TEST PARAMETERS AND RESULTS

Column No.	HSS Dimensions (mm)	Steel Bars (%)	Concrete Strength		Factored Resistance*		Test Load	Load Intensity		Fire Resistance (hr:min)	
			28 days (MPa)	test date (MPa)	C'r (kN)	Crc (kN)	C (kN)	C/C'r	C/Crc	Calculated	Measured
1	273.1 dia × 6.35	2.3	42.3	46.7	1110	2851	1050	0.95	0.37	2:27	3:08
2	273.1 dia × 6.35	2.3	42.3	47.0	1110	2851	1900	1.71	0.67	1:28	1:36

*Factored Resistance:

C'r = Factored compressive resistance of concrete core of column according to CAN3-S16.1-M89

Crc = Factored compressive resistance of concrete-filled HSS column according to CAN3-S16.1-M89

APPENDIX: MATERIAL PROPERTIES AND SPECIFICS OF COLUMNS AND FURNACE

The values of the material properties used in this study are the same as those used in References 8 and 14 for the calculation of the fire resistance of reinforced concrete columns and concrete-filled steel columns, with the exception of the thermal properties of the concrete. These properties, which in References 8 and 14 apply to siliceous aggregate concrete, have been replaced by those of carbonate aggregate concrete, which have been measured recently.

CONCRETE PROPERTIES

Stress-strain relations

for $\varepsilon_c \leq \varepsilon_{max}$

$$f_c = f_c' \left[1 - \left(\frac{\varepsilon_{max} - \varepsilon_c}{\varepsilon_{max}} \right)^2 \right]$$
(25)

for $\varepsilon_c > \varepsilon_{max}$

$$f_c = f_c' \left[1 - \left(\frac{\varepsilon_c - \varepsilon_{max}}{3\varepsilon_{max}} \right)^2 \right]$$
(26)

where

$$\varepsilon_{max} = 0.0025 + (6.0T + 0.04T^2) \times 10^{-6}$$
(27)

and

for $0°C < T < 450°C$

$$f_c' = f_{co}'$$
(28)

for $450°C \leq T \leq 874°C$

$$f_c = f_{co}' \left[2.011 - 2.353 \left(\frac{T-20}{1000} \right) \right]$$
(29)

for $T > 874°C$

$$f_c' = 0$$
(30)

Thermal capacity

for $0 \leq T \leq 400°C$

$$\rho_c c_c = 2.566 \times 10^6 \quad J\ m^{-3}°C^{-1}$$
(31)

for $400 < T \leq 410°C$

$$\rho_c c_c = (0.1765T - 68.034) \times 10^6 \quad J\ m^{-3}°C^{-1}$$
(32)

for $410 < T \leq 445°C$

$$\rho_c c_c = (-0.05043T + 25.00671) \times 10^6 \quad J\ m^{-3}°C^{-1}$$
(33)

for $445 < T \leq 500°C$

$$\rho_c c_c = 2.566 \times 10^6 \quad J\,m^{-3}°C^{-1} \tag{34}$$

for $500 < T \leq 635°C$

$$\rho_c c_c = (0.01603T - 5.44881) \times 10^6 \quad J\,m^{-3}°C^{-1} \tag{35}$$

for $635 < T \leq 715°C$

$$\rho_c c_c = (0.16635T - 100.90225) \times 10^6 \quad J\,m^{-3}°C^{-1} \tag{36}$$

for $715 < T \leq 785°C$

$$\rho_c c_c = (-0.22103T + 176.07343) \times 10^6 \quad J\,m^{-3}°C^{-1} \tag{37}$$

for $T > 785°C$

$$\rho_c c_c = 2.566 \times 10^6 \quad J\,m^{-3}°C^{-1} \tag{38}$$

Thermal conductivity

for $0 \leq T \leq 293°C$

$$k_c = 1.355 \quad W\,m^{-1}°C^{-1} \tag{39}$$

for $T > 293°C$

$$k_c = -0.001241T + 1.7162 \quad W\,m^{-1}°C^{-1} \tag{40}$$

Coefficient of thermal expansion

$$\alpha_c = (0.008T + 6) \times 10^{-6} \quad °C^{-1} \tag{41}$$

STEEL PROPERTIES

Stress-strain relations

for $\varepsilon_s \leq \varepsilon_p$

$$f_y = \frac{f(T,0.001)}{0.001} \varepsilon_s \tag{42}$$

where

$$\varepsilon_p = 4 \times 10^{-6} f_{yo} \tag{43}$$

and

$$f(T,001) = (50 - 0.04T) \times \left[1 - \exp\!\left((-30 + 0.03T)\sqrt{0.001}\right)\right] \times 6.9 \tag{44}$$

for $\varepsilon_s > \varepsilon_p$

$$f_y = \frac{f(T,0.001)}{0.001} \varepsilon_p + f(T,(\varepsilon_s - \varepsilon_p + 0.001)) - f(T,0.001) \tag{45}$$

where

$$f(T, (\varepsilon_s - \varepsilon_p + 0.001)) = (50 - 0.04T) \times [1 - \exp((-30 + 0.03T)\sqrt{(\varepsilon_s - \varepsilon_p + 0.001)})] \times 6.9 \quad (46)$$

Thermal capacity

for $0°C \leq T \leq 650°C$

$$\rho_s c_s = (0.004T + 3.3) \times 10^6 \quad J \, m^{-3}°C^{-1} \quad (47)$$

for $650°C < T \leq 725°C$

$$\rho_s c_s = (0.068T + 38.3) \times 10^6 \quad J \, m^{-3}°C^{-1} \quad (48)$$

for $725°C < T \leq 800°C$

$$\rho_s c_s = (-0.086T + 73.35) \times 10^6 \quad J \, m^{-3}°C^{-1} \quad (49)$$

for $T > 800°C$

$$\rho_s c_s = 4.55 \times 10^6 \quad J \, m^{-3}°C^{-1} \quad (50)$$

Thermal conductivity

for $0°C \leq T \leq 900°C$

$$k_s = -0.022T + 48 \quad W \, m^{-1}°C^{-1} \quad (51)$$

for $T > 900°C$

$$k_s = 28.2 \quad W \, m^{-1}°C^{-1} \quad (52)$$

Coefficient of thermal expansion

for $T < 1000°C$

$$\alpha_s = (0.004T + 12) \times 10^{-6} \quad °C^{-1} \quad (53)$$

for $T \geq 1000°C$

$$\alpha_s = 16 \times 10^{-6} \quad °C^{-1} \quad (54)$$

WATER PROPERTIES

Thermal capacity

$$\rho_w c_w = 4.2 \times 10^6 \quad J \, m^{-3}°C^{-1} \quad (55)$$

Heat of vaporization

$$\lambda_w = 2.3 \times 10^6 \quad J \, kg^{-1} \quad (56)$$

SPECIFICS OF COLUMN AND FIRE

ε_f = emissivity of fire: 0.75

ε_s = emissivity of steel: 0.80

KL = effecitve length of columns: 2.0 m for fire resistance calculations

l = length of column that contributes to axial deformation: 3.5 m

ϕ = concentration of moisture in concrete by volume: 0.10
